Objective Email: tutorcs@163.com

This lab takes as input a CSV (comma separated values) file (.csv extension) that is used for generating tabular data in spreadsheets. *Specifically, for this assignment, you will NEED to assume this CSV file was generated in Windows* (the reason will be explained Shortly). Consider the *data.csv* file below as it appears when you open it in Excert as an example.

		А	В	
ht	1	Kruger Industrial Smoothing	365	
	2	Kruger Industrial Smoothing Smeridautores.co		
	3	Vandelay Industries	500	
	4	Pendant Publishing	100	
	5	J. Peterman Catalog	42	
	6			

Figure 1 data.csv file in Excel

This file shows the stock returns from an investment portfolio over a year. "A" column contains the stock name and "B" column indicates the returns in USD (*We will assume that there is no negative stock return in all our CSV files*). Then running the *lab4w23_testbench.asm* file in RARS that takes *data.csv* as the input CSV file should yield the following analysis:

- 1. Find the total file size in bytes (excluding any metadata generated by your OS)
- 2. Calculate the total income generated from all stocks
- 3. Find the stock that gave maximum returns and the one with minimum returns...

When we run (*the completed*) *lab4w23_testbench.asm* in RARS, we should get the output console as shown below.

Figure 2 After running the lab4w23_testbench.asm file with the Lab4 assignment fully completed

About the Windows CSV file format

To distinguish between each ency/rownetord of the tyreadsheet format of the CSV file, the following convention is adopted depending on the OS:

Windows - Lines end with both a <CR> followed by a <LF> character

Linux - Lines end with only a SLF> character Macintosh (Mac OSX) And Subschlight Character Lines end with only a SCR> character Lines end with only a SCR> character

where <CR> is the carriage return ('\1') character and <LF> is the line feed/newline ('\n') character. LULOTCS in the line feed/newline ('\n') character.

If you open the provided *data.csv* file in Notepad++ on Windows with "Show all Characters" enabled, then you should get the following view showing the placement of the carriage return and line feed characters.

Figure 3 data.csv on Notepad++ on Windows

So, for example, if I were to express record 2 from *data.csv* as a string of characters in RARS, I would write: "Kramerica,0\r\n". If you are using an OS that is NOT Windows, it is likely that *data.csv* would not open correctly due to the encoding differences. If you have a text editor like Notepad++ that allows you to see all characters, make sure that the "\r\n" appears for each record in the file as shown in Figure 3.

Another assumption that we will state at this point is that we expect that in each record, the name of the stock is followed by the "," and then <u>immediately</u> by the stock price expressed as an <u>unsigned</u> integer in base 10. So, with record 2 as an example, we will never have a situation where it is written as "Kramerica, ... 0\r\n" where the 2 red dots indicate two black spaces. This assumption will make the CSV file analysis by RARS a bit easier to code.

Resources 程序代写代做 CS编程辅导

Much like how a high-level program has a specific file extension (.c for C, .py for python) RARS based RISC-V programs have an .asm extension.

In the Lab4 folder in Lab4 folder in the Lab4 folde

- 1. add_function.asm wo integers as user inputs and prints their addition result. The actual addition is function, sum. Sum accepts two arguments in the a0, a1 registers and returns a0
- 2. multiply_function.a. Land accepts two integers as user inputs and prints their multiplication result. The actual multiplication is done through calling a function, multiply. Multiply accepts two arguments in the a0, a1 registers and returns a0*a1 in a0 register. This function in turn calls the function sum, described previously to do a particular addition. Thus, multiply function is an example of a nested function cut, a function which itself calls another function, sum in our case.
- 3. RISC-V_function_convention.pdf This pdf describes the conventions of how we use the various 32 RV64I registers in terms of creating a program with multiple functions. The documentation is provided such that students can start working an implementing the required function for Lab4. Studying the comments in add_function.asm alongside reading this pdf should be sufficient to create the required functions for this assignment.
- 4. lab4w23_testbench.am That is the that testbench Sregam you will cook completion of all coding in Lab4 to ensure your Lab4 assignment works as expected. This file is initially provided such that if you run it as it is(with the other asm files in the same directory), you will still get correctly generated output as a string 3 to 5 function allocate_file_record_pointers from allocate_file_record_pointers sam is contenned.
- 5. allocate_file_record_pointers.asm This .asm file contains a function that creates an internal reference table in memory that points to the location of the start of a string indicating stock name and the start of the stock price to take and every record-entry in that lata.csv file. This function has been fully written out for you. You must not edit or modify this file.
- 6. *income_from_record.asm* This. asm file contains a function that **you will write** to convert the string data from the income of a record/entry in the spreadsheet and convert it into an integer. Example, convert the string "1234" into the actual integer 1234 in base 10.
- 7. length_of_file.asm This. asm file contains a function that **you will write** to find the total amount of data bytes in the csv file. Refer to Figure 2 for an example.
- 8. *maxIncome.asm* This. asm file contains a function that **you will write** to determine the name of the stock that has the maximum income in the csv file. Refer to Figure 2 for an example.
- 9. *minIncome.asm* This. asm file contains a function that **you will write** to determine the name of the stock that has the minimum income in the csv file. Refer to Figure 2 for an example.
- 10. *totalIncome.asm* This. asm file contains a function that **you will write** to sum up all the stock incomes in the csv file. Refer to Figure 2 for an example.

Please download these files and make sure to open them in **RARS Text editor only**. Else the comments

and other important code sections won't be properly highlighted and can be a hindrance to learning assembly language intuiting.

These 9 files have enough comments in the source code to jumpstart your understanding of RISC-V assembly programming for Lab 4 if the lectures have not yet covered certain topics in assembly programming.

Beyond these three file the three file the required resources in the Lecture Slides themselves, in the ppt files which the file three which the file three which the file three slides are very self-explanatory and it is that the file three slides are very start reading them even if the instructor hasn't started discussing them in lect

For the usage of macro avily in this lab to generate ecalls), please also refer to the RARS documentation on macros and ecalls as well.

Memory arrangemental actine Stute of CS

The memory of RISC V is used as per the given requirements.

Figure 4 data segment window for MMIO after running completed Lab4 assignment.

This is achieved by running the provided fileRead macro in lab4w23 testbench.asm.

For reference, from Fragre 4, note the first record in the given *data.csv* file, "Kruger Industrial Smoothing,365\r\n". The location of the letter 'K'(encoded in ASCI as byte 0x4b or 64 in base 10) is 0xffff0000. The location of the character digit '3', i.e. the start of the income,(encoded in ASCI as byte 0x33 or 51 in base 10) tis 0xffff001c. If you count the bytes in the string "Kruger Industrial Smoothing,365\r\n" with "K peing the 0th character, then 3' is the 28th character (0x1c), so this makes sense.

File Record Pointers

We need a systematic way to reference the memory locations of both the stock name and income from the file buffer at 0xffff0000. Remember that the stock names and stock incomes can be both of varying lengths of characters. Thus, we set aside the memory location 0x10040000 (heap) for a table containing the locations of the first character appearing in the stock name and income respectively of each record in the CSV file.

Address	Value (+0)	Value (+4)	Value (+8)	Value (+c)	Value (+10)	Value (+14)	Value (+18)	Value (+1c)
0x10040000	0xffff0000	0xffff001c	0xffff0021	0xffff002b	0xffff002e	0xffff0042	0xffff0047	0xffff005a
0x10040020	0xffff005f	0xffff0073	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000

Figure 5 data segment window for heap after running completed Lab4 assignment.

This is achieved by running the provided function *allocate_file_record_pointers* in *lab4w23_testbench.asm* with the arguments in a0 and a1 registers being the file size in bytes (119 in our given example from *data.csv*) and the starting address of file buffer (0x0ffff0000 in our given example from *data.csv*), respectively. The *allocate_file_record_pointers* function is provided in the *allocate_file_record_pointers.asm* file separately through the .include statement in

For reference, from Figure 5, note in data.csv the first record's location of start of income name (0xffff0000) and income value(0xffff001c) are stored as words in consecutive heap memory locations 0x10040000 and 0x10040004 respectively Likewise, the second record's (i.e. "Kramerica,0\r\n") location of start of income nan consecutive heap memory locations 0x4000c respectively. And so on and so forth. It is left as a

CSV file and how they
5, the 10 non zero heap
10/2 = 5 records in our

204000c respectively. And so on and so forth. *It is left as a dent verifies this pattern for the remaining records in the emory locations as shown in Figure 5.* As we see in Figure n 0x10040000 to 0x10040024 indicate there were originally e (no. of records) is returned in a0.

Student coded lunc

All student coded functions are to be written in the .asm files listed in the <code>lab4w23_testbench.asm</code> file using the .include statement (excluding <code>allocate_file_record_pointers.asm</code>). The functions written MUST abide by the register saving conventions as outlined in RISG V function_convention.pdf.

- 1. length_of_file(a1) This function is to be written in length_of_file.asm. It accepts as argument in a1 register the buffer address holding file data and returns in a0 the length of the file data in bytes.

 From our example involving data of the file of the file of the file data in bytes.
- 2. income_from_record.asm. It accepts as argument in a0 register the pointer to start of numerical income in a record. It returns the income's numerical value in a0. Email: tutorcs@163.com

From our example involving data.csv, income_from_record(0x10040004)=365. This is the income from the stock of Kruger Industrial Smoothing. income_from_record(0x1004000c)= 0. This is the income from the stock of Kramfrida $\frac{749389476}{749389476}$

You may use the *mul* instruction if you feel your student code involves the multiplication operation.

3. **totalIncome(a0,a1)** This function is to be written in *totalIncome.asm.* a0 contains the file record pointer array location (0x10040000 in our example) But your code MUST handle any address value. a1 contains the number of records in the CSV file. a0 then returns the total income (add up all the record incomes).

From our example involving data.csv, totalIncome(0x10040000, 5)= 1007

4. **maxIncome(a0,a1)** - This function is to be written in *maxIncome.asm*. a0 contains the file record pointer array location (0x10040000 in our example) But your code MUST handle any address value. a1 contains the number of records in the CSV file. a0 then returns the heap memory pointer to the actual location of the record stock name in the file buffer.

From our example involving *data.csv*, maxIncome(0x10040000, 5)= 0x10040010. Observe from Figure 5 that this address value points to the location of the stock name "Vandelay Industries", which is valued at the maximum value of \$500, and <u>proving that even in times of market uncertainty</u>, the latex polymer industry is booming as ever.

5. minIncome(a0,a1) - This function is to be written in minIncome.asm. a0 contains the file record pointer array location (0x10040000 in our example) But your code MUST handle any address value. a1

contains the number of records in the CSV file. a0 then returns the heap memory pointer to the actual location of the record storenary and file of the CS编程期·

From our example involving data.csv, maxIncome(0x10040000, 5)= 0x10040008. Observe from Figure 5 that this address value points to the location of the stock name "Kramerica", which is valued at the minimum value of \$0, all, a sales pitch about a "coffee table book about coffee tables" is an absolutely

Test Cases

The Lab4 folder in Google Drive contains some test cases in the testCases subfolder for the case when filePath is changed to data2.csv and data3.csv respectively in lab4w23 testbench.asm. The corresponding output that was obtained for these two files from running lab4w23 testbench.asm for them is provided in this syptoter as well

A Note About Academic Integrity

This is the lab assignment where most students continue to get flagged for cheating. Please review the pamphlet on Academic Dishonesty and look at the examples in the first lecture for acceptable and unacceptable collaboration.

You should be doing this assignment completely all by yourself!

Grading Rubric (100 points total)

The following rubric applies provided you have fulfilled all criteria in Minimum Submission **Requirements.** Failing any criteria listed in that section would result in an automatic grade of zero which cannot be eligible for applying for a regrade request.

20 pt lab4w23_testbench.asm assembles without errors (so even if you submit lab4w23_testbench.asm with his heavier Equival as these Complete punished you, you would still get 20 pts!)

80 pt output in file *lab3 output.txt* matches the specification:

Remember that you will but the finite for the minimum points. There is no need to then run it for the minimum points.

The testbench, with the other .asm files left as it is, is supposed to give an error when it tries to access either the maxIncome of mining functions. You need to correctly implement those two bifore you see a fully working testbench.

Note however that even when you *do* run the given testbench, you should still see some deliverable output.

Email: tutorcs@163.com

For example, here's the I/O console when I run the testbench as is. You will see that every code before line 126 9as you exit maxIncome function) has been executed correctly:

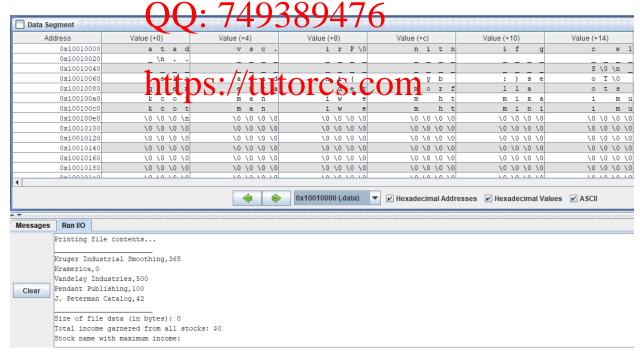

Figure 6 Running the testbench without modifying any of the starter code files results in partial output delivered but enough to give you a starting idea!

<u>Click here</u> for the Regrade Request Form. Only those regrade requests that were submitted *within 1 week* of having received your Lab 3 grade (an announcement would be made on Piazza) will be considered. Else it will be ignored.

Legal Notice

All course materials ar in the Lab4 folder in the course Google Drive must not be shared by the students gain. Thus, if any of t found in any type of public domain site or for financial found in any type of publicly available site (e.g., GitHub, stack Exchange), or for monetary gain (e.g., Chegg), then the original poster will be cited for misusing CSE12 course-based content and will be reported to UCSC for academic dishonesty.

In the case of sites such as Chegg.com, we have been able to locate course material shared by a previous quarter student. Chegg contact with the proof of the student's misconduct leading to an automatic failing grade in the course.
